

User Story: AI Job Workspace

Overview

The AI Job Workspace transforms a job posting into an interactive preparation hub where users can optimize their application and prepare for interviews without leaving the application.

Instead of requiring users to manually copy information between multiple AI tools, the platform automatically extracts job information and provides personalized actions tailored to that specific position.

The feature integrates the application's existing AI capabilities into a single workflow centered around a real job opportunity.

Business Objective

Increase user engagement by allowing users to import real job opportunities directly into the application and receive AI-powered guidance throughout the entire application process.

The feature positions the application as an end-to-end career preparation platform rather than only an interview preparation tool.

User Story

As a job seeker,

I want to import a job posting into the application,

so that I can immediately analyze my resume, improve my application documents, and prepare for the interview using AI specifically tailored to that position.

Supported Job Sources

Users can create a Job Workspace using any of the following methods:

1. Job URL

The user pastes a public job posting URL.

Examples include:

- LinkedIn Jobs
- Company career websites
- Any publicly accessible job posting

The backend retrieves the page and extracts structured job information.

2. Manual Job Description

The user pastes the complete job description directly into the application.

The backend analyzes the content and generates the same structured job representation used for imported URLs.

3. Share From External Applications

Users can share job postings directly from supported applications using the operating system's Share functionality.

Example:

LinkedIn Jobs

Share

↓

Open with Interview App

↓

Job imported automatically

This provides the fastest and most seamless user experience.

Backend Responsibilities

The backend is responsible for transforming raw job data into a standardized internal format.

Regardless of the input method, the backend should extract:

- Job title
- Company name
- Location
- Employment type
- Seniority level
- Required skills
- Preferred skills
- Responsibilities
- Qualifications
- Technologies
- Soft skills
- Salary (when available)
- Experience level
- Education requirements
- Application URL
- Original source
- Posting metadata

The mobile application should never perform job parsing.

Job Workspace

After processing, the application presents a dedicated Job Workspace.

This becomes the central screen for all AI-powered actions related to the imported job.

The original job description remains available for reference throughout the workflow.

Job Details Screen

The Job Details screen displays:

Job Information

- Job title
- Company
- Location

- Employment type
 - Seniority
 - Technologies
 - Required skills
 - Preferred qualifications
 - Full job description
-

AI Actions

The application prominently presents the following actions.

1. Score My CV

The user's resume is evaluated against the imported job.

The AI produces:

- Overall ATS compatibility score
- Skill matching analysis
- Missing keywords
- Strengths
- Weaknesses
- Section-by-section evaluation
- Recommendations for improvement

This is the primary call-to-action for the feature.

2. Improve My CV

Using both the imported job description and the user's current resume, the AI generates an optimized version tailored to the role.

Potential improvements include:

- Stronger professional summary
 - Better achievement wording
 - Improved keyword coverage
 - Skill prioritization
 - Experience optimization
 - ATS-friendly formatting recommendations
-

3. Generate Cover Letter

Generate a personalized cover letter based on:

- Imported job
- Company information
- User resume
- User profile

The cover letter is tailored specifically to the position rather than being generic.

4. Interview Preparation

Generate a complete AI interview using the imported job description.

The existing interview engine should be reused.

The backend should:

Job

↓

Extract skills

↓

Map to interview topics

↓

Generate interview questions

↓

Start interview session

The interview focuses on the responsibilities and technologies described in the imported posting.

5. Study Plan (Optional)

Generate a personalized learning roadmap identifying the skills required to become a stronger candidate for the selected position.

The study plan may include:

- Missing technologies
 - Suggested learning order
 - Estimated study time
 - Interview focus areas
 - Practice recommendations
-

User Journey

Import Job

Backend extracts structured job information

Job Workspace

Score CV

Improve CV

Generate Cover Letter

Prepare for Interview

Follow Personalized Study Plan

The workflow is intentionally designed to guide users through the complete application process, from resume optimization to interview preparation.

Mobile Responsibilities

The mobile application should support:

Job Import

- Paste job URL
 - Paste job description
 - Receive shared jobs from external applications
 - Display processing status
-

Job Workspace

Display:

- Job details
 - Required skills
 - AI action cards
 - Saved job information
-

AI Feature Navigation

Launch:

- ATS scoring
- CV improvement
- Cover letter generation
- Interview preparation
- Study plan

The mobile application should remain responsible only for presentation and workflow orchestration. AI processing and document analysis should be handled by backend services.

Backend Responsibilities

The backend should expose services for:

Job Processing

- Import job from URL

- Import manual description
 - Parse and normalize job data
 - Store imported jobs
 - Refresh job information (future)
-

AI Services

- ATS resume scoring
- Resume optimization
- Cover letter generation
- Interview generation
- Personalized study plan generation (Optional)

Each service should consume the standardized job model rather than the original raw job posting.

Business Rules

- All imported jobs should be converted into a common internal data structure.
- The same AI services must work regardless of how the job was imported.
- Job parsing and AI generation occur exclusively on backend services.
- Imported jobs should be reusable without requiring users to import them again.
- Users may import multiple jobs and maintain separate workspaces for each application.
- AI-generated content should always be based on the latest imported job data.
